#### **OUESTION**

Suppose  $X_1, X_2, X_3$  and  $X_4$  are independent and identically distributed random variables, having density function f. Then,

A) 
$$\Pr(X_4 > Max(X_1, X_2) > X_3) = \frac{1}{6}$$
  
B)  $\Pr(X_4 > Max(X_1, X_2) > X_3) = \frac{1}{8}$   
C)  $\Pr(X_4 > X_3 > Max(X_1, X_2)) = \frac{1}{12}$   
D)  $\Pr(X_4 > X_3 > Max(X_1, X_2)) = \frac{1}{6}$ 

B) 
$$Pr(X_4 > Max(X_1, X_2) > X_3) = \frac{1}{8}$$

C) 
$$Pr(X_4 > X_3 > Max(X_1, X_2)) = \frac{1}{12}$$

D) 
$$Pr(X_4 > X_3 > Max(X_1, X_2)) = \frac{1}{6}$$

#### SOLUTION

Given,  $X_1, X_2, X_3, X_4$  are i.i.d random variables.

Lemma 0.1. Every i.i.d sequence of random variables is exchangeable. Any value of a finite sequence is as likely as any permutation of those values. The joint probability distribution is invariant under the symmetric group.

Proof.

$$f_{X_1,X_2,X_3,...,X_n}(x) = f_{X_1}(x) \times f_{X_2}(x) \times \dots f_{X_n}(x)$$
 (0.0.1)

As  $X_i$ s are i.i.d random variables, their joint probability density function is the product of their marginal probability density functions and as multiplication is commutative, it is exchangeable.

**Definition 1** (Symmetric Group). It is the group of permutation on a set with n elements and has n! elements. Order of a symmetric group represents the number of elements in it.

**Lemma 0.2.** If n elements of a set are random, then probability of each element 'E<sub>i</sub>' of the symmetric group 'S' is  $\frac{1}{n!}$ .

*Proof.* As the *n* values are completely random, there will be no bias for a particular arrangement and hence all the elements of the symmetric group are equally likely.

$$O(S) = n! \tag{0.0.2}$$

where: O(S) denotes the order of the symmetric group.

$$\implies \Pr(E_i) = \frac{1}{n!} \forall E_i \in S$$
 (0.0.3)

Hence, any permutation of  $X_1, X_2, X_3, X_4$  is equally likely. As there are 4 random values that the random variables represent, they can be arranged in 4! ways. By (0.0.3), we have:

$$Pr(X_1 > X_2 > X_3 > X_4) = Pr(X_1 > X_2 > X_4 > X_3)$$
(0.0.4)

$$=\frac{1}{24}$$
 (0.0.6)

#### 1) Options A and B:

$$Pr(X_4 > Max(X_1, X_2) > X_3) = Pr(X_4 > Max(X_1, X_2) > X_3 | X_1 > X_2) + Pr(X_4 > Max(X_1, X_2) > X_3 | X_2 > X_1) (0.0.7)$$

Clearly, by definition:

$$Max(X_1, X_2) = \begin{cases} X_1, & \text{if } X_1 > X_2 \\ X_2, & \text{if } X_2 > X_1 \end{cases}$$
 (0.0.8)

$$\Rightarrow \Pr(X_4 > Max(X_1, X_2) > X_3) =$$

$$\Pr(X_4 > X_1 > X_3) +$$

$$\Pr(X_4 > X_2 > X_3) \quad (0.0.9)$$

$$Pr(X_4 > X_1 > X_3) = Pr(X_4 > X_1 > X_2 > X_3)$$
$$+ Pr(X_4 > X_1 > X_3 > X_2) = \frac{1}{12} \quad (0.0.10)$$

As  $Max(X_1, X_2)$  being  $X_1$  or  $X_2$  is equally

1

likely,

$$\Pr\left(X_4 > X_2 > X_3\right) = \frac{1}{12} \tag{0.0.11}$$

$$\Pr(X_4 > Max(X_1, X_2) > X_3) = 2 \times \frac{1}{12} = \frac{1}{6}$$
(0.0.12)

## 2) Options C and D:

$$Pr(X_4 > X_3 > Max(X_1, X_2)) =$$

$$Pr(X_4 > X_3 > Max(X_1, X_2)|X_1 > X_2) +$$

$$Pr(X_4 > X_3 > Max(X_1, X_2)|X_2 > X_1) \quad (0.0.13)$$

$$Pr(X_4 > X_3 > Max(X_1, X_2)) =$$

$$Pr(X_4 > X_3 > X_1 > X_2) +$$

$$Pr(X_4 > X_3 > X_2 > X_1) \quad (0.0.14)$$

$$\Pr(X_4 > X_3 > Max(X_1, X_2)) = 2 \times \frac{1}{24} = \frac{1}{12}$$
(0.0.15)

Answer: Option (A) and (C)
